Cabling and bracing support trees with co-dominant stems, weak **insured tree service roswell ga** unions or a history of splitting. Steel or synthetic cable is installed high in the crown to limit movement, while bracing rods bolt a union together lower down. Both are arborist-level work: the hardware must be sized to the tree, installed at the correct height, and inspected every few years. Cabling does not save a tree with root failure, and it is not a substitute for removal when a target sits underneath. Ask %LINK% whether an ISA-certified arborist is specifying the system and who inspects it later.
